Abstract

We present an explicit on-shell framework to renormalize the Cabibbo-Kobayashi-Maskawa (CKM) quark mixing matrix at the one-loop level. It is based on a novel procedure to separate the external-leg mixing corrections into gauge-independent self-mass (sm) and gauge-dependent wave-function renormalization contributions, and to adjust non-diagonal mass counterterm matrices to cancel all the divergent sm contributions, and also their finite parts subject to constraints imposed by the hermiticity of the mass matrices. It is also shown that the proof of gauge independence and finiteness of the remaining one-loop corrections to $W \to q_i + \overline{q}_j$ reduces to that in the unmixed, single-generation case. Diagonalization of the complete mass matrices leads then to an explicit expression for the CKM counterterm matrix, which is gauge independent, preserves unitarity, and leads to renormalized amplitudes that are non-singular in the limit in which any two fermions become mass degenerate.

I. INTRODUCTION

The Cabibbo-Kobayashi-Maskawa (CKM) [1] quark mixing matrix is one of the basic pillars of the electroweak sector of the Standard Model (SM). In fact, the detailed determination of this matrix is one of the major aims of recent experiments carried out at the B factories [2], as well as the objective of a wide range of theoretical studies [2, 3, 4].

An important theoretical problem associated with the CKM matrix is its renormalization. An early discussion, in the two-generation framework, was presented in Ref. [5], which focused mostly on the removal of the ultraviolet (UV) divergent contributions. In recent years there have been a number of interesting analyses that address the renormalization of both the UV-divergent and finite contributions at various levels of generality and complexity [6].

In Ref. [7], we outlined an explicit and direct on-shell framework to renormalize the CKM matrix at the one-loop level, which can be regarded as a simple generalization of Feynman's approach in Quantum Electrodynamics (QED) [8].

In the present paper, we present a detailed discussion of this renormalization framework and of the calculations underpinning its implementation. We recall that, in QED, the self-energy insertion in an external leg involving an outgoing fermion is of the form

$$\Delta\mathcal{M}^{\rm leg} \;=\; \overline{u}(p)\Sigma(\not{p})\frac{1}{\not{p}-m}, \tag{1}$$

$$\Sigma(\not{p}) \;=\; A + B(\not{p}-m) + \Sigma_{\rm fin}(\not{p}), \tag{2}$$

where $u(p)$ is the spinor of the external particle, $\Sigma(\not{p})$ the self-energy, $i(\not{p}-m)^{-1}$ the particle's propagator, A and B UV-divergent constants, and $\Sigma_{\rm fin}(\not{p})$ the finite part that behaves as $\Sigma_{\rm fin}(\not{p}) \propto (\not{p}-m)^2$ in the neighborhood of $\not{p}=m$. The contribution of A to Eq. (1) exhibits a pole as $\not{p}\to m$, while the term proportional to B is regular in this limit and that involving $\Sigma_{\rm fin}(\not{p})$ clearly vanishes. We may refer to A and B as the "self-mass" (sm) and "wave-function renormalization" (wfr) contributions, respectively. The contribution A is gauge independent and is canceled by the mass counterterm. The contribution B is in general gauge dependent but, since the $(\not{p}-m)$ factor cancels the propagator's singularity, in Feynman's approach it is combined with the proper vertex diagrams leading to a gauge-independent result. In other formulations, B in Eq. (2) is canceled by an explicit field renormalization counterterm δZ, which also modifies the tree-level vertex coupling and, consequently, transfers once more

this contribution to the vertex amplitude.

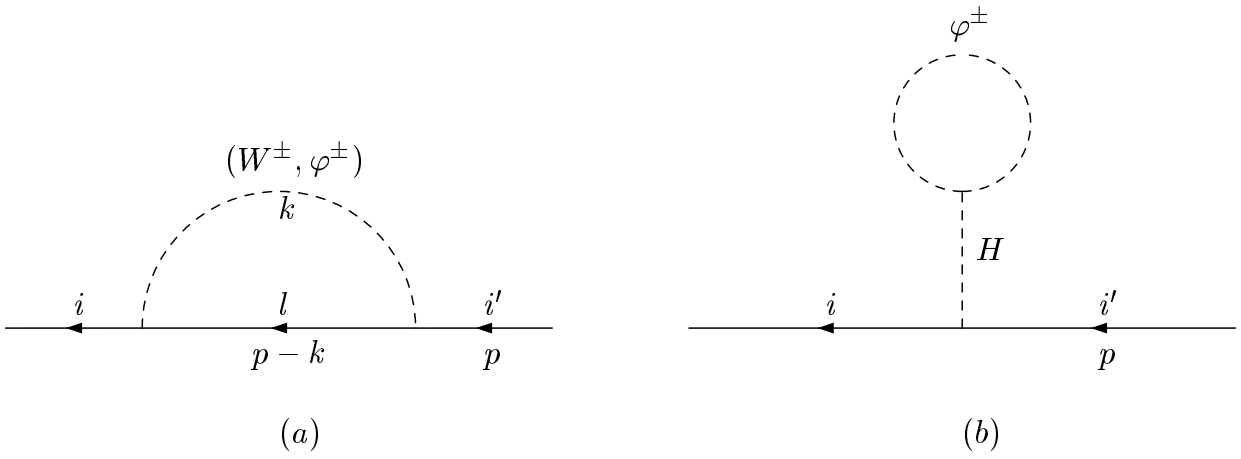

FIG. 1: Fermion self-energy diagrams.

In the case of the CKM matrix we encounter off-diagonal as well as diagonal external-leg contributions generated by virtual effects involving $W^\pm$ bosons and charged Goldstone bosons ($\phi^\pm$). As a consequence, the self-energy corrections to an external leg involving an outgoing quark is of the form

$$\Delta\mathcal{M}^{\rm leg}_{ii'} = \overline{u}_i(p)\Sigma_{ii'}(\not{p})\frac{1}{\not{p}-m_{i'}}, \tag{3}$$

where i denotes the external quark of momentum p and mass m_i, i' the initial virtual quark of mass $m_{i'}$, $i(\not{p}-m_{i'})^{-1}$ is the corresponding propagator, and $\Sigma_{ii'}(\not{p})$ the self-energy (see Fig. 1). In Fig. 1(b) we have included the tadpole diagram involving a virtual $\phi^\pm$ boson because its contribution is necessary to remove the gauge dependence in the diagonal contributions of Fig. 1(a).

There are other contributions involving virtual effects of Z^0 bosons, neutral Goldstone bosons (ϕ^0), photons (γ), and Higgs bosons (H) as well as additional tadpole diagrams, but all of these lead to diagonal expressions of the usual kind. An analytic expression for the full result may be found, e.g., in Ref. [9].

In Sec. II A we analyze in detail the contributions arising from the diagrams in Fig. 1. After carrying out the Dirac algebra in a way that treats the i and i' quarks on an equal footing, we find that the $\Sigma_{ii'}(\not{p})$ contributions can be classified as follows: (i) terms with a left factor $(\not{p}-m_i)$; (ii) terms with a right factor $(\not{p}-m_{i'})$; (iii) terms with a left factor $(\not{p}-m_i)$ and a right factor $(\not{p}-m_{i'})$; and (iv) constant terms not involving $\not{p}$.

We note that, in Eq. (3), $\Sigma_{ii'}(\not{p})$ is inserted between the external-quark spinor $\overline{u}_i(p)$ and the virtual-quark propagator $i(\not{p} - m_{i'})^{-1}$. It follows that off-diagonal contributions of class (i) vanish in Eq. (3), since $(\not{p} - m_{i'})^{-1}$ is non-singular for $i' \neq i$, while $\overline{u}_i(p)(\not{p} - m_i) = 0$. However, there are in general diagonal contributions of class (i), since for $i' = i$ the factor $(\not{p} - m_i)$ may cancel against the propagator in Eq. (3). In contributions of class (ii), the right factor $(\not{p} - m_{i'})$ cancels the propagator in Eq. (3). In analogy with the cancellation of $\Sigma_{\text{fin}}(\not{p})$ in Eqs. (1) and (2), contributions of class (iii) vanish in both the diagonal and off-diagonal cases, since the right factor $(\not{p} - m_{i'})$ cancels the propagator in Eq. (3), and again $\overline{u}_i(p)(\not{p} - m_i) = 0$. A common feature of all the non-vanishing contributions to Eq. (3) arising from classes (i) and (ii) is that the virtual-quark propagator $i(\not{p} - m_{i'})^{-1}$ has been canceled in both the diagonal ($i' = i$) and off-diagonal ($i' \neq i$) cases and, as a consequence, they are non-singular as $\not{p} \to m_{i'}$. Thus, they can be suitably combined with the proper vertex diagrams, in analogy with B in QED. In contrast, the contributions of class (iv) to Eq. (3) retain the virtual-quark propagator $i(\not{p} - m_{i'})^{-1}$ and are singular in this limit.

In Sec. II A we show that, in our formulation, the contributions to Eq. (3) of class (iv) are gauge independent, while those arising from classes (i) and (ii) contain gauge-dependent pieces.

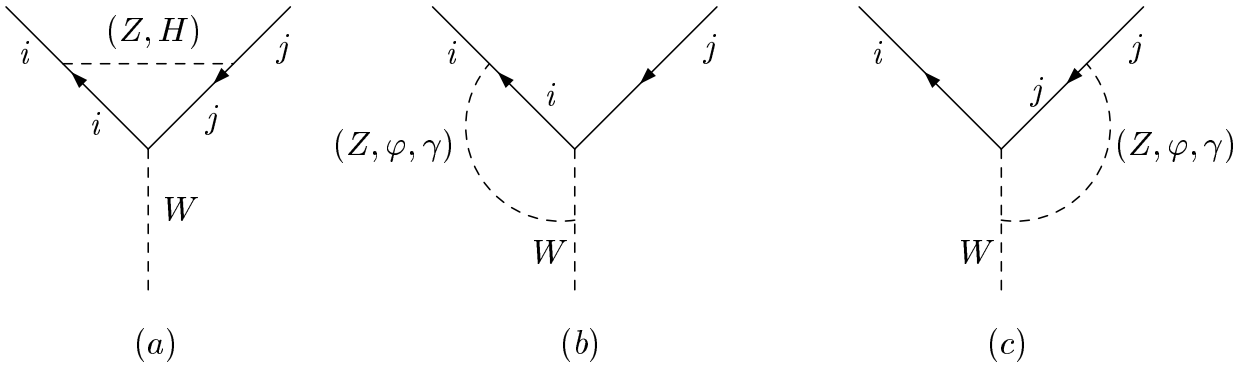

FIG. 2: Proper $Wq_i\overline{q}_j$ vertex diagrams.

In analogy with the QED case, we identify class (iv) and classes (i) and (ii) as self-mass (sm) and wave-function renormalization (wfr) contributions, respectively. They are listed explicitly in Secs. II B and II C. In Sec. II C, we also discuss important simplifications that occur in the wfr contributions to the physical $W \to q_i + \overline{q}_j$ amplitude. In particular, we show that the gauge-dependent and the UV-divergent parts of these contributions depend

only on the external-quark masses m_i and m_j and do not involve the CKM matrix elements, except for an overall factor V_{ij}, in analogy with the proper vertex diagrams depicted in Fig. 2. This result implies that, once the divergent sm contributions are removed in the renormalization process, the proof of finiteness and gauge independence of the remaining one-loop corrections to the $W \to q_i + \overline{q}_j$ amplitude is the same as in the much simpler case of a hypothetical single generation made of the i and j quarks with unit CKM coupling.

By contrast, since the sm contributions to Eq. (1) are proportional to $(\not{p} - m_{i'})^{-1}$, they have a structure unsuitable for the combination with vertex diagrams. Thus, one expects such terms to be separately gauge independent, as we find.

The plan of this paper is the following. In Sec. II we evaluate the diagrams depicted in Fig. 1 and prove the various properties described above. In Sec. III we study the cancellation of sm contributions by suitably adjusting the mass counterterms, subject to restrictions imposed by hermiticity. In Sec. IV we discuss the diagonalization of the complete mass matrix, i.e. the renormalized plus counterterm mass matrices, and show explicitly how this procedure generates a CKM counterterm matrix in a manner that preserves unitarity and gauge independence. Section V contains our conclusions.

II. EVALUATION OF $\Sigma_{ii'}(\not{p})$ AND GAUGE INDEPENDENCE OF THE SELF-MASS CONTRIBUTIONS

In subsection II A we evaluate the one-loop diagrams of Fig. 1, explain the separation into wfr and sm amplitudes, and show explicitly the cancellation of gauge dependences in the latter. Following standard conventions, $\Sigma_{ii'}(\not{p})$ is defined as i times the diagrams of Fig. 1.

We show how the various contributions can be classified in the categories (i)–(iv) described in Sec. I. As explained in Sec. I, terms of class (iii) give a vanishing contribution to the correction $\Delta\mathcal{M}^{\rm leg}_{ii'}$ associated with an external leg, while those belonging to classes (i) and (ii) effectively cancel the virtual-quark propagator $i(\not{p}-m_{i'})^{-1}$. They naturally combine with the proper vertex diagrams and are identified with wfr contributions. They are generally gauge dependent. By contrast, in our formulation, the contributions of class (iv) to $\Delta\mathcal{M}^{\rm leg}_{ii'}$ are gauge independent and proportional to $i(\not{p}-m_{i'})^{-1}$, with a cofactor that is independent of $\not{p}$ although it depends on the chiral projectors $a_\pm$. They are identified with sm contributions.

The sm and wfr contributions to $\Delta\mathcal{M}^{\rm leg}_{ii'}$ are given explicitly in subsections II B and II C.

Although the main focus of this paper is the study of the sm contributions, in Sec. II C we also digress on the further simplifications of the wfr contributions that occur in the important $W \to q_i + \overline{q}_j$ amplitude.

A. Evaluation of $\Sigma_{ii'}(\not{p})$

For definiteness, we first consider the case in which i and i' in Fig. 1(a) are up-type quarks and l is a down-type quark. Following standard conventions, we denote by V_{il} the CKM matrix element involving the up-type quark i and the down-type quark l. Simple modifications in other cases are discussed in Sec. II D.

Writing the W-boson propagator in the R_ξ gauge as

$$\mathcal{D}^W_{\mu\nu} = -i\frac{g_{\mu\nu} - k_\mu k_\nu(1-\xi_W)/(k^2 - m_W^2\xi_W)}{k^2 - m_W^2}, \tag{4}$$

where ξ_W is the gauge parameter, we first consider the contribution to Fig. 1(a) of the second, ξ_W-dependent term. We call this contribution $M^{\rm GD}_{ii'}(W)$, where the notation reminds us that this is the gauge-dependent part of the W-boson contribution. After some elementary algebra, we find

$$\begin{aligned} M^{\rm GD}_{ii'}(W) \;=\; & \frac{g^2}{2} V_{il}V^\dagger_{li'}(1-\xi_W)\int_n \frac{1}{(k^2-m_W^2)\,(k^2-m_W^2\xi_W)} \\ & \times a_+\left[-\not{k} - \not{p} - m_l + (\not{p}-m_l)\frac{1}{\not{p}-\not{k}-m_l}(\not{p}-m_l)\right]a_-, \end{aligned} \tag{5}$$

where $a_\pm = (1 \pm \gamma_5)/2$, $\int_n = \mu^{4-n}\int d^nk/(2\pi)^n$, and μ is the 't Hooft mass scale. The term proportional to $\not{k}$ cancels, since the integrand is odd under $\not{k} \to -\not{k}$, and the m_l term cancels because of the chiral projectors. We rewrite $\not{p}a_-$ as follows:

$$\begin{aligned} 2\not{p}a_- \;&=\; \not{p}a_- + a_+\not{p} \\ &=\; (\not{p}-m_i)a_- + a_+(\not{p}-m_{i'}) + m_i a_- + m_{i'}a_+, \end{aligned} \tag{6}$$

so that the i and i' quarks are treated on an equal footing. In the terms not involving m_l, we employ the unitarity relation,

$$V_{il}V^\dagger_{li'} = \delta_{ii'}, \tag{7}$$

and $M^{\rm GD}_{ii'}(W)$ becomes

$$M^{\rm GD}_{ii'}(W) \;=\; \frac{g^2}{2}(1-\xi_W)\int_n \frac{1}{(k^2-m_W^2)\,(k^2-m_W^2\xi_W)}\left\{-\frac{\delta_{ii'}}{2}[a_+(\not p-m_i)+(\not p-m_i)a_- + m_i] + V_{il}V^\dagger_{li'}a_+(\not p-m_l)\frac{1}{\not p-\not k-m_l}(\not p-m_l)a_-\right\}. \tag{8}$$

The tadpole diagram of Fig. 1(b) contributes

$$M^{\rm tad}_{ii'}(\phi) = -\frac{g^2 m_i}{4m_W^2}\delta_{ii'}\int_n \frac{1}{k^2-m_W^2\xi_W}. \tag{9}$$

Its combination with the term proportional to $\delta_{ii'}m_i$ in Eq. (8) gives

$$-\frac{g^2 m_i}{4m_W^2}\delta_{ii'}\int_n \frac{1}{k^2-m_W^2}, \tag{10}$$

a gauge-independent amplitude. Thus,

$$\begin{aligned} M^{\rm GD}_{ii'}(W)+M^{\rm tad}_{ii'}(\phi) &= -\frac{g^2 m_i}{4m_W^2}\delta_{ii'}\int_n \frac{1}{k^2-m_W^2} \\ &- \frac{g^2}{4}\delta_{ii'}(1-\xi_W)\int_n \frac{1}{(k^2-m_W^2)\,(k^2-m_W^2\xi_W)}[a_+(\not p-m_i)+(\not p-m_i)a_-] \\ &+ \frac{g^2}{2}V_{il}V^\dagger_{li'}(1-\xi_W)\int_n \frac{1}{(k^2-m_W^2)\,(k^2-m_W^2\xi_W)}a_+(\not p-m_l)\frac{1}{\not p-\not k-m_l}(\not p-m_l)a_-. \end{aligned} \tag{11}$$

Using the relations

$$\begin{aligned} a_+(\not p-m_l) &= (\not p-m_i)a_- + m_i a_- - m_l a_+, \\ (\not p-m_l)a_- &= a_+(\not p-m_{i'}) + m_{i'}a_+ - m_l a_-, \end{aligned} \tag{12}$$

the last term of Eq. (11) may be written as

$$\begin{aligned} M^{\rm last}_{ii'} \;=\; & \frac{g^2}{2}V_{il}V^\dagger_{li'}(1-\xi_W)\int_n \frac{1}{(k^2-m_W^2)\,(k^2-m_W^2\xi_W)}[(\not p-m_i)a_- + m_i a_- - m_l a_+] \\ & \times \frac{1}{\not p-\not k-m_l}[a_+(\not p-m_{i'}) + m_{i'}a_+ - m_l a_-]. \end{aligned} \tag{13}$$

On the other hand, the contribution $M_{ii'}(\phi)$ to diagram 1(a) arising from the $\phi^\pm$ boson is

$$M_{ii'}(\phi) = \frac{g^2}{2m_W^2}V_{il}V^\dagger_{li'}\int_n \frac{1}{k^2-m_W^2\xi_W}(m_i a_- - m_l a_+)\frac{1}{\not p-\not k-m_l}(m_{i'}a_+ - m_l a_-). \tag{14}$$

Its combination with the term proportional to

$$(m_i a_- - m_l a_+)\frac{1}{\not p-\not k-m_l}(m_{i'}a_+ - m_l a_-) \tag{15}$$

in Eq. (13) leads to a gauge-independent amplitude.

Combining these results, we have

$$
\begin{aligned}
M^{\rm GD}_{ii'}(W) + M^{\rm tad}_{ii'}(\phi) + M_{ii'}(\phi) &= -\frac{g^2 m_i}{4m_W^2}\delta_{ii'}\int_n \frac{1}{k^2-m_W^2} \\
&+ \frac{g^2}{2m_W^2}V_{il}V^\dagger_{li'}\int_n \frac{1}{k^2-m_W^2}(m_i a_- - m_l a_+)\frac{1}{\not p - \not k - m_l}(m_{i'}a_+ - m_l a_-) \\
&- \frac{g^2}{4}\delta_{ii'}(1-\xi_W)\int_n \frac{1}{(k^2-m_W^2)\,(k^2-m_W^2\xi_W)}[a_+(\not p - m_i) + (\not p - m_i)a_-] \\
&+ \frac{g^2}{2}V_{il}V^\dagger_{li'}(1-\xi_W)\int_n \frac{1}{(k^2-m_W^2)\,(k^2-m_W^2\xi_W)}\left[(\not p - m_i)a_-\frac{1}{\not p - \not k - m_l}a_+(\not p - m_{i'})\right. \\
&\left.+ (\not p - m_i)a_-\frac{1}{\not p - \not k - m_l}(m_{i'}a_+ - m_l a_-) + (m_i a_- - m_l a_+)\frac{1}{\not p - \not k - m_l}a_+(\not p - m_{i'})\right]. \qquad (16)
\end{aligned}
$$

The contribution of the gauge-independent part of the W-boson propagator, i.e. the first term in Eq. (4), leads to

$$
M^{\rm GI}_{ii'}(W) = -\frac{g^2}{2}V_{il}V^\dagger_{li'}\int_n \frac{1}{k^2-m_W^2}a_+\gamma^\mu\frac{1}{\not p - \not k - m_l}\gamma_\mu a_-. \qquad (17)
$$

In order to classify the various contributions according to the discussion of Sec. I, we evaluate the integral that appears in Eq. (17) and in the second term of Eq. (16):

$$
\begin{aligned}
K(\not p, m_l) &= \int_n \frac{1}{(k^2-m_W^2)\,(\not p - \not k - m_l)} \\
&= -\frac{i}{16\pi^2}\left\{\not p[\Delta + I(p^2,m_l) - J(p^2,m_l)] + m_l[2\Delta + I(p^2,m_l)]\right\}, \qquad (18)
\end{aligned}
$$

where

$$
\begin{aligned}
\Delta &= \frac{1}{n-4} + \frac{1}{2}[\gamma_E - \ln(4\pi)] + \ln\frac{m_W}{\mu}, \qquad (19) \\
\{I(p^2,m_l); J(p^2,m_l)\} &= \int_0^1 dx\,\{1;x\}\ln\frac{m_l^2 x + m_W^2(1-x) - p^2x(1-x) - i\varepsilon}{m_W^2}. \qquad (20)
\end{aligned}
$$

Next, we insert Eq. (18) into the second term of Eq. (16) and into Eq. (17) and finally add Eqs. (16) and (17). Treating the terms involving $\not p a_-$ and $\not p a_+$ in the symmetric way explained before Eq. (7), evaluating the integral $\int_n (k^2-m_W^2)^{-1}$ and employing once more the unitarity relation (7) in some of the m_l-independent terms, we find that the complete

contribution from Figs. 1(a) and (b) can be expressed in the form:

$$
\begin{aligned}
M_{ii'}^{(1)} &= M_{ii'}^{\rm GD}(W) + M_{ii'}^{\rm GI}(W) + M_{ii'}^{\rm tad}(\phi) + M_{ii'}(\phi) \\
&= \frac{ig^2}{32\pi^2} V_{il} V_{li'}^\dagger \left\{ -m_i \left(1 + \frac{m_i^2}{2m_W^2}\Delta \right) \right. \\
&\quad + \frac{m_l^2}{2m_W^2}(m_i a_- + m_{i'} a_+)[3\Delta + I(p^2, m_l) + J(p^2, m_l)] \\
&\quad - \left[m_i a_- + m_{i'} a_+ + \frac{m_i m_{i'}}{2m_W^2}(m_i a_+ + m_{i'} a_-) \right] [I(p^2, m_l) - J(p^2, m_l)] \\
&\quad - \frac{1}{2m_W^2} \left[m_i m_{i'} ((\not{p} - m_i) a_+ + a_-(\not{p} - m_{i'})) + m_l^2 ((\not{p} - m_i) a_- + a_+(\not{p} - m_{i'})) \right] \\
&\quad \times [\Delta + I(p^2, m_l) - J(p^2, m_l)] \\
&\quad - [(\not{p} - m_i) a_- + a_+(\not{p} - m_{i'})] \left[\Delta + \frac{1}{2} + I(p^2, m_l) - J(p^2, m_l) \right] \\
&\quad + i8\pi^2 (1 - \xi_W) \int_n \frac{1}{(k^2 - m_W^2)(k^2 - m_W^2 \xi_W)} [a_+ \left(\not{p} - m_{i'} \right) + (\not{p} - m_i) a_-] \\
&\quad - i16\pi^2 (1 - \xi_W) \int_n \frac{1}{(k^2 - m_W^2)(k^2 - m_W^2 \xi_W)} \\
&\quad \times \left[(\not{p} - m_i) a_- \frac{1}{\not{p} - \not{k} - m_l} a_+ (\not{p} - m_{i'}) + (\not{p} - m_i) a_- \frac{1}{\not{p} - \not{k} - m_l} (m_{i'} a_+ - m_l a_-) \right. \\
&\quad \left. \left. + \ (m_i a_- - m_l a_+) \frac{1}{\not{p} - \not{k} - m_l} a_+ (\not{p} - m_{i'}) \right] \right\}. \qquad (21)
\end{aligned}
$$

The last two terms in Eq. (21) are gauge dependent and include a left factor $(\not{p} - m_i)$ or a right factor $(\not{p} - m_{i'})$ or both. Thus, they belong to the classes (i), (ii), or (iii) discussed in Sec. I. The integrals in these two terms can readily be evaluated using the identity

$$
\frac{1 - \xi_W}{(k^2 - m_W^2)(k^2 - m_W^2 \xi_W)} = \frac{1}{m_W^2} \left[\frac{1}{k^2 - m_W^2} - \frac{1}{k^2 - m_W^2 \xi_W} \right] \qquad (22)
$$

and Eq. (18). We find

$$
i8\pi^2 (1 - \xi_W) \int_n \frac{1}{(k^2 - m_W^2)(k^2 - m_W^2 \xi_W)} = \Delta - \frac{1}{2} - \xi_W \left(\Delta - \frac{1}{2} + \frac{1}{2} \ln \xi_W \right), \qquad (23)
$$

$$
\begin{aligned}
L(\not{p}, m_l, \xi_W) &\equiv i16\pi^2 (1 - \xi_W) \int_n \frac{1}{(k^2 - m_W^2)(k^2 - m_W^2 \xi_W)(\not{p} - \not{k} - m_l)} \\
&= \frac{1}{m_W^2} \int_0^1 dx \, [\not{p}(1 - x) + m_l] \ln \frac{m_l^2 x + m_W^2 \xi_W (1 - x) - p^2 x (1 - x) - i\varepsilon}{m_l^2 x + m_W^2 (1 - x) - p^2 x (1 - x) - i\varepsilon}. \qquad (24)
\end{aligned}
$$

If i is an outgoing, on-shell up-type quark, the external-leg amplitude is obtained by multiplying Eq. (21) on the left by $\overline{u}_i(p)$, the spinor of the outgoing quark, and on the right by $i(\not{p} - m_{i'})^{-1}$, the propagator of the initial virtual quark. Thus, the relevant amplitude

associated with the external leg is

$$\Delta\mathcal{M}^{\rm leg}_{ii'} = \overline{u}_i(p) M^{(1)}_{ii'} \frac{i}{\not{p} - m_{i'}}. \tag{25}$$

This brings about important simplifications. Using the well-known rules to treat indeterminate factors of the form $\overline{u}_i(p)(\not{p} - m_i)(\not{p} - m_i)^{-1}$ [8, 10], one readily finds the following identities for both diagonal ($i' = i$) and off-diagonal ($i' \neq i$) contributions:

$$\overline{u}_i(p)[(\not{p} - m_i)a_\pm + a_\mp(\not{p} - m_{i'})]\frac{i}{\not{p} - m_{i'}} = i\overline{u}_i(p)a_\mp, \tag{26}$$

$$\overline{u}_i(p)(\not{p} - m_i)O_1(\not{p} - m_{i'})\frac{i}{\not{p} - m_{i'}} = 0, \tag{27}$$

$$\begin{aligned}&\overline{u}_i(p)[(\not{p} - m_i)a_- L(\not{p}, m_l, \xi_W)(m_{i'}a_+ - m_l a_-) + (m_i a_- - m_l a_+)L(\not{p}, m_l, \xi_W)a_+(\not{p} - m_{i'})] \\ &\times\frac{i}{\not{p} - m_{i'}} = i\overline{u}_i(p)(m_i a_- - m_l a_+)L(\not{p}, m_l, \xi_W)a_+,\end{aligned} \tag{28}$$

where O_1 is a generic Dirac operator that is regular in the limit $\not{p} \to m_{i'}$ and $L(\not{p}, m_l, \xi_W)$ is the integral defined in Eq. (24). These identities tell us that terms in $M^{(1)}_{ii'}$ of class (iii) give a vanishing contribution to $\Delta\mathcal{M}^{\rm leg}_{ii'}$ (cf. Eq. (27)), while those of classes (i) and (ii) combine to cancel the $(\not{p} - m_{i'})^{-1}$ factor in Eq. (25) (cf. Eqs. (26) and (28)).

In the second and third terms of Eq. (21), we expand the functions $I(p^2, m_l)$ and $J(p^2, m_l)$ about $p^2 = m_i^2$. The lowest-order term, with p^2 set equal to m_i^2, is independent of $\not{p}$ and, therefore, belongs the class (iv). The same is true of the other contributions in the first two terms of Eq. (21). They lead to a multiple of $i(\not{p} - m_{i'})^{-1}$ in Eq. (25) with a cofactor that involves the chiral projectors $a_\pm$, but is independent of $\not{p}$. Thus, they belong to class (iv) and are identified as the sm contributions. The terms of $\mathcal{O}\left(p^2 - m_i^2\right)$ in the expansions of $I(p^2, m_l)$ and $J(p^2, m_l)$ give only diagonal contributions ($i' = i$) to Eq. (25), belong to class (i) because $p^2 - m_i^2 = (\not{p} - m_i)(\not{p} + m_i)$, and cancel the $(\not{p} - m_i)^{-1}$ factor in Eq. (25). Terms of $\mathcal{O}\left(\left(p^2 - m_i^2\right)^2\right)$ and higher in this expansion give vanishing contributions to $\Delta\mathcal{M}^{\rm leg}_{ii'}$.

As mentioned before, the terms of classes (i) and (ii) in $M^{(1)}_{ii'}$ (including those generated by the expansions of $I(p^2, m_l)$ and $J(p^2, m_l)$) are identified as wfr contributions. In contrast to the sm contributions, they contain gauge-dependent parts (cf. the last two terms in Eq. (21)). Both the sm and wfr contributions contain UV divergences.

B. Self-Mass Contributions

The sm contributions $\Delta\mathcal{M}_{ii'}^{\rm leg,sm}$ to the external-leg correction for an outgoing on-shell up-type quark i are obtained by inserting the first three terms of Eq. (21) with p^2 set equal to m_i^2 into Eq. (25):

$$\begin{aligned}\Delta\mathcal{M}_{ii'}^{\rm leg,sm} \;=\; & \frac{g^2}{32\pi^2}V_{il}V_{li'}^{\dagger}\overline{u}_i(p)\left\{m_i\left(1+\frac{m_i^2}{2m_W^2}\Delta\right)\right.\\ & -\frac{m_l^2}{2m_W^2}(m_i a_- + m_{i'}a_+)\left[3\Delta + I\left(m_i^2,m_l\right)+J\left(m_i^2,m_l\right)\right]\\ & +\left[m_i a_- + m_{i'}a_+ + \frac{m_i m_{i'}}{2m_W^2}(m_i a_+ + m_{i'}a_-)\right]\\ & \left.\times\left[I\left(m_i^2,m_l\right)-J\left(m_i^2,m_l\right)\right]\right\}\frac{1}{\not p - m_{i'}}. \end{aligned} \tag{29}$$

The amplitudes $I\left(m_i^2,m_l\right)$ and $J\left(m_i^2,m_l\right)$, defined in Eq. (20), are real except when $m_i = m_t$ corresponding to an external on-shell top quark. The diagonal contributions in this case include imaginary parts that cannot be removed by a mass counterterm, in conjunction with a singular propagator. The problem arises because, in the usual calculation of its decay rate, the top quark is treated as an asymptotic state, rather than an unstable particle. In analogy with the case of the Z^0 boson, its proper treatment examines the resonance region in the virtual propagation of the top quark between its production and decay vertices. One finds that, in the narrow-width approximation, in which contributions of next-to-next-to-leading order are neglected, $\mathrm{Im}\,\Sigma(m_t)$ is related to the total decay width Γ_t by the expression $\mathrm{Im}\,\Sigma(m_t) = -\Gamma_t[1-\mathrm{Re}\,\Sigma'(m_t)]$ and provides the $i\Gamma_t$ term in the resonance amplitude. The latter is proportional to $i(\not p - m_t + i\Gamma_t)^{-1}[1-\mathrm{Re}\,\Sigma'(m_t)]^{-1}$, where the first factor is the resonant propagator and the second one the wfr term that contributes to the top-quark couplings to the external particles in the production and decay vertices. Since the imaginary parts of $I\left(m_t^2,m_l\right)$ and $J\left(m_t^2,m_l\right)$ in the diagonal top-quark contributions are effectively absorbed in the $i\Gamma_t$ term in the resonance propagator, we remove them from Eq. (29). Specifically, in the diagonal contributions to Eq. (29) involving an external top quark, $I\left(m_t^2,m_l\right)$ and $J\left(m_t^2,m_l\right)$ are replaced by their real parts.

We see that Eq. (29) satisfies the basic properties explained before: it is a multiple of the virtual-quark propagator $i(\not p - m_{i'})^{-1}$ with a cofactor that is gauge and momentum independent. As expected in a chiral theory, it involves the $a_\pm$ projectors.

C. Wave-Function Renormalization Contributions

For completeness, we exhibit the wfr contributions $\Delta\mathcal{M}_{ii'}^{\rm leg,wfr}$ to the external-leg correction. They are obtained by inserting the last four terms of Eq. (21) into Eq. (25), employing the identities of Eqs. (26)–(28), and incorporating the diagonal contributions arising from the expansions of $I(p^2,m_l)$ and $J(p^2,m_l)$ in the second and third terms of Eq. (21):

$$\begin{aligned}\Delta\mathcal{M}_{ii'}^{\rm leg,wfr} \;=\; & \frac{g^2}{32\pi^2}V_{il}V_{li'}^{\dagger}\overline{u}_i(p)\left\{\left[I\left(m_i^2,m_l\right)-J\left(m_i^2,m_l\right)\right]a_+\right. \\ & +\frac{1}{2m_W^2}(m_im_{i'}a_-+m_l^2a_+)\left[\Delta+I\left(m_i^2,m_l\right)-J\left(m_i^2,m_l\right)\right] \\ & -\delta_{ii'}\frac{m_i^2m_l^2}{2m_W^2}\left[I'\left(m_i^2,m_l\right)+J'\left(m_i^2,m_l\right)\right]+\delta_{ii'}m_i^2\left(1+\frac{m_i^2}{2m_W^2}\right) \\ & \times\left[I'\left(m_i^2,m_l\right)-J'\left(m_i^2,m_l\right)\right]+\left[\xi_W\left(\Delta+\frac{1}{2}\ln\xi_W-\frac{1}{2}\right)+1\right]a_+ \\ & \left.-\,N(m_i,m_l,\xi_W)a_+\right\}, \end{aligned} \tag{30}$$

where

$$\left\{I'\left(m_i^2,m_l\right);J'\left(m_i^2,m_l\right)\right\}=-\int_0^1\frac{dx\,\{1;x\}x(1-x)}{m_l^2x+m_W^2(1-x)-m_i^2x(1-x)-i\varepsilon} \tag{31}$$

are the derivatives of $I(p^2,m_l)$ and $J(p^2,m_l)$ with respect to p^2, evaluated at $p^2=m_i^2$, and

$$N(m_i,m_l,\xi_W)=\frac{1}{m_W^2}\int_0^1 dx\,\left[m_i^2(1-x)-m_l^2\right]\ln\frac{m_l^2x+m_W^2\xi_W(1-x)-m_i^2x(1-x)-i\varepsilon}{m_l^2x+m_W^2(1-x)-m_i^2x(1-x)-i\varepsilon}. \tag{32}$$

The previous to last term in Eq. (30) was obtained by using Eqs. (23) and (26), and combining the result with other Δ-dependent contributions. The last term in Eq. (30) was obtained by using Eqs. (24) and (28), and carrying out some elementary Dirac algebra. Employing Eq. (7) in m_l-independent terms, we see that the UV-divergent part in Eq. (30) is given by

$$\Delta\mathcal{M}_{ii'}^{\rm leg,wfr,div}=\frac{g^2}{32\pi^2}V_{il}V_{li'}^{\dagger}\overline{u}_i(p)\Delta\left[\frac{m_i^2}{2m_W^2}a_-+\left(\xi_W+\frac{m_l^2}{2m_W^2}\right)a_+\right], \tag{33}$$

which contains both diagonal and off-diagonal pieces. In particular, the diagonal part of Eq. (33) contains a gauge-dependent contribution, while the off-diagonal term is gauge independent.

We now digress on the further simplifications that take place when Eq. (30) is inserted in the physical $W\to q_i+\overline{q}_j$ amplitude. In this case, Eq. (30) is multiplied on the right by $(-ig/\sqrt{2})V_{i'j}\gamma^\mu a_-v_j\epsilon_\mu$, where v_j is the spinor associated with the $\overline{q}_j$ quark and ϵ^μ is the

polarization four-vector of the W boson. Because of the chiral projectors, the contribution of the term proportional to $(m_i m_{i'}/2m_W^2)a_-[\Delta + I - J]$ vanishes. Next, we note that the first, second, fifth, and sixth terms between curly brackets in Eq. (30) are independent of i'. Denoting these contributions as $f(m_i, m_l)$ and employing the unitarity relation (7), we have $V_{il}V_{li'}^\dagger V_{i'j} f(m_i, m_l) = V_{il}\delta_{lj} f(m_i, m_l) = V_{ij} f(m_i, m_j)$. Thus, the contributions of these terms to the $W \to q_i + \overline{q}_j$ amplitude are proportional to V_{ij} and depend only on the external-fermion masses m_i and m_j. The same is true of the corresponding contributions arising from the $\overline{q}_j$ external leg. We emphasize that this result includes all the gauge-dependent and all the UV-divergent contributions in Eq. (30). This important property is shared by the proper vertex diagrams of Fig. 2, which are also proportional to V_{ij} and depend only on m_i and m_j. As explained in Sec. I, this property implies that, once the divergent sm contributions are canceled by renormalization, the proof of finiteness and gauge independence of the remaining one-loop corrections to the $W \to q_i + \overline{q}_j$ amplitude is the same as in the single-generation case.

Although the contributions to the $W \to q_i + \overline{q}_j$ amplitude from the terms involving $I'(m_i^2, m_l)$ and $J'(m_i^2, m_l)$ in Eq. (30) are not simplified by the unitarity relations without appealing to suitable approximations, we note that they are finite and gauge independent. It is important to point out that the simplifications we encountered in the $W \to q_i + \overline{q}_j$ amplitude depend crucially on the fact that the wfr terms cancel the virtual-quark propagator $i(\not{p} - m_{i'})^{-1}$.

D. Other Cases

Equations (29) and (30) exhibit the sm and wfr contributions to the external-leg corrections in the case of an outgoing on-shell up-type quark i. Here i' labels the initial virtual up-type quark in Fig. 1(a) and l the down-type quark in the loop.

The corresponding expressions for an incoming up-type quark can be gleaned by multiplying Eq. (21) by $u_{i'}(p)$ on the right and by $i(\not{p} - m_i)^{-1}$ on the left. Interchanging i and i', it is easy to see that the sm contributions for an incoming up-type quark are obtained from Eq. (29) by substituting $V_{il}V_{li'}^\dagger \to V_{i'l}V_{li}^\dagger$, interchanging $a_- \leftrightarrow a_+$ between the curly brackets, and multiplying the resulting expression by $u_i(p)$ on the right and by $(\not{p} - m_{i'})^{-1}$ on the left. Similarly, the wave-function renormalization for an incoming up-type quark is

obtained from Eq. (30) by substituting $V_{il}V_{li'}^{\dagger} \to V_{i'l}V_{li}^{\dagger}$, interchanging $a_- \leftrightarrow a_+$ between the curly brackets, and multiplying the resulting expression by $u_i(p)$ on the right. The expressions for an incoming (outgoing) up-type antiquark are the same as those for an outgoing (incoming) up-type quark with the substitution $u_i(p) \to v_i(-p)$, the negative-energy spinor. In the case of antiquarks, p in these expressions is identified with the four-momentum in the direction of the arrows in the Feynman diagrams, which is minus the four-momentum of the antiparticle. Finally, the expression for an outgoing down-type quark is obtained from that of an outgoing up-type quark by substituting $V_{il}V_{li'}^{\dagger} \to V_{jl}^{\dagger}V_{lj'}$, where j and j' denote the on-shell and virtual down-type quarks, respectively, and l the up-type quark in the loop. The other down-type-quark amplitudes are obtained from the corresponding up-type-quark expressions in a similar manner.

III. MASS RENORMALIZATION

In order to generate mass counterterms suitable for the renormalization of the sm contributions shown in Eq. (29), we may proceed as follows. In the weak-eigenstate basis, the bare mass matrices $m_0'^Q$ for the up- and down-type quarks ($Q = U, D$) are non-diagonal, and the corresponding terms in the Lagrangian density may be written as $-\overline{\psi}_R'^Q m_0'^Q \psi_L'^Q + \text{h.c.}$, where $\psi_L'^Q$ and $\psi_R'^Q$ are left- and right-handed column spinors that include the three up-type (or down-type) quarks. Decomposing $m_0'^Q = m'^Q - \delta m'^Q$, where m'^Q and $\delta m'^Q$ are identified as the renormalized and counterterm mass matrices, we envisage a biunitary transformation of the quark fields that diagonalizes m'^Q, leading to a renormalized mass matrix m^Q that is diagonal, real and endowed with positive entries. The same operation transforms $\delta m'^Q$ into a new matrix δm^Q which, in general, is non-diagonal. In the new framework, which we may identify as the mass-eigenstate basis, the mass term is given by

$$-\overline{\psi}\left(m - \delta m^{(-)}a_- - \delta m^{(+)}a_+\right)\psi = -\overline{\psi}_R\left(m - \delta m^{(-)}\right)\psi_L - \overline{\psi}_L\left(m - \delta m^{(+)}\right)\psi_R, \qquad (34)$$

where m is real, diagonal, and positive, and $\delta m^{(-)}$ and $\delta m^{(+)}$ are arbitrary non-diagonal matrices subject to the hermiticity constraint

$$\delta m^{(+)} = \delta m^{(-)\dagger}. \qquad (35)$$

This constraint follows from the requirement that the mass terms in the Lagrangian density, displayed in Eq. (34), must be hermitian. In order to simplify the notation, we do not

exhibit the label Q, but it is understood that Eq. (34) represents two different mass matrices involving the up- and down-type quarks.

As is customary, the mass counterterms are included in the interaction Lagrangian. Their contribution to Eq. (25) is given by

$$i\overline{u}_i(p)\left(\delta m^{(-)}_{ii'}a_- + \delta m^{(+)}_{ii'}a_+\right)\frac{i}{\not{p}-m_{i'}}. \tag{36}$$

We now adjust $\delta m^{(-)}_{ii'}$ and $\delta m^{(+)}_{ii'}$ to cancel, as much as possible, the sm contributions given in Eq. (29). The cancellation of the UV-divergent parts is achieved by choosing

$$\begin{aligned}
\left(\delta m^{(-)}_{\rm div}\right)_{ii'} &= \frac{g^2 m_i}{64\pi^2 m_W^2}\Delta\left(\delta_{ii'}m_i^2 - 3V_{il}V^\dagger_{li'}m_l^2\right),\\
\left(\delta m^{(+)}_{\rm div}\right)_{ii'} &= \frac{g^2 m_{i'}}{64\pi^2 m_W^2}\Delta\left(\delta_{ii'}m_i^2 - 3V_{il}V^\dagger_{li'}m_l^2\right),
\end{aligned} \tag{37}$$

It is important to note that

$$\left(\delta m^{(+)}_{\rm div}\right)_{ii'} = \left(\delta m^{(-)}_{\rm div}\right)^*_{i'i}, \tag{38}$$

so that $\delta m^{(+)}_{\rm div}$ and $\delta m^{(-)}_{\rm div}$ satisfy the hermiticity requirement of Eq. (35).

In order to discuss the cancellation of the finite parts, we call ii' channel the amplitude in which i labels the outgoing, on-shell up-type quark and i' the initial, virtual one (cf. Fig. 1). Then the $i'i$ channel is the amplitude in which the roles are reversed: i' is the outgoing, on-shell quark, while i is the initial, virtual one.

Comparing Eq. (29) with Eq. (36), we see that a complete cancellation of the sm corrections for an outgoing up-type quark or an incoming up-type antiquark in the ii' channel is achieved by adjusting the mass counterterms according to

$$\begin{aligned}
\delta m^{(-)}_{ii'} &= \frac{g^2 m_i}{32\pi^2}\left\{\delta_{ii'}\left(1+\frac{m_i^2}{2m_W^2}\Delta\right) - V_{il}V^\dagger_{li'}\frac{m_l^2}{2m_W^2}\left[3\Delta + I\left(m_i^2,m_l\right) + J\left(m_i^2,m_l\right)\right]\right.\\
&\quad \left. + V_{il}V^\dagger_{li'}\left(1+\frac{m_{i'}^2}{2m_W^2}\right)\left[I\left(m_i^2,m_l\right) - J\left(m_i^2,m_l\right)\right]\right\},\\
\delta m^{(+)}_{ii'} &= \frac{g^2 m_{i'}}{32\pi^2}\left\{\delta_{ii'}\left(1+\frac{m_i^2}{2m_W^2}\Delta\right) - V_{il}V^\dagger_{li'}\frac{m_l^2}{2m_W^2}\left[3\Delta + I\left(m_i^2,m_l\right) + J\left(m_i^2,m_l\right)\right]\right.\\
&\quad \left. + V_{il}V^\dagger_{li'}\left(1+\frac{m_i^2}{2m_W^2}\right)\left[I\left(m_i^2,m_l\right) - J\left(m_i^2,m_l\right)\right]\right\}.
\end{aligned} \tag{39}$$

Once $\delta m^{(-)}_{ii'}$ and $\delta m^{(+)}_{ii'}$ are fixed, the mass counterterms for the reverse $i'i$ channel are determined by the hermiticity condition of Eq. (35), to wit

$$\delta m^{(-)}_{i'i} = \delta m^{(+)*}_{ii'}, \qquad \delta m^{(+)}_{i'i} = \delta m^{(-)*}_{ii'}. \tag{40}$$

Since the functions I and J in Eq. (29) are evaluated at $p^2 = m_i^2$ in the ii' channel and at $p^2 = m_{i'}^2$ in the $i'i$ channel, we see that the mass counterterms in Eqs. (39) and (40) cannot remove completely the sm contributions in both amplitudes. Taking into account this restriction, we choose the following renormalization prescription.

Writing the mass counterterm matrix for the up-type quark in the explicit form

$$\begin{pmatrix} \delta m_{uu} & \delta m_{uc} & \delta m_{ut} \\ \delta m_{cu} & \delta m_{cc} & \delta m_{ct} \\ \delta m_{tu} & \delta m_{tc} & \delta m_{tt} \end{pmatrix}, \tag{41}$$

where $\delta m_{ii'} = \delta m_{ii'}^{(-)} a_- + \delta m_{ii'}^{(+)} a_+$ $(i, i' = u, c, t)$, we choose δm_{uu}, δm_{cc}, and δm_{tt} to cancel, as is customary, all the diagonal contributions in Eq. (29). For the non-diagonal entries, we choose δm_{uc}, δm_{ut}, and δm_{ct} to cancel completely the contributions in Eq. (29) corresponding to the uc, ut, and ct channels, respectively. The remaining mass counterterms, δm_{cu}, δm_{tu}, and δm_{tc} are then fixed by the hermiticity condition in Eq. (35). This implies that the finite parts of the sm corrections in the cu, tu, and tc channels are not fully canceled. However, after the mass renormalization is implemented, the residual contributions from Eq. (29) to the $W \to q_i + \overline{q}_j$ amplitudes are finite, gauge independent, and very small in magnitude (see Appendix A). In fact, they are of second (first) order in the small ratios m_q^2/m_W^2 $(q \neq t)$ when the top quark is not (is) the external particle and, furthermore, they include small CKM matrix elements.

An analogous approach is followed for the down-type-quark mass counterterms. We call $j'j$ channel the amplitude involving an incoming, on-shell down-type quark j and a virtual down-type quark j'. In analogy with Eq. (39), the complete cancellation of the sm corrections for an incoming down-type quark (or an outgoing down-type antiquark) in the $j'j$ channel is implemented by choosing:

$$\begin{aligned}
\delta m_{j'j}^{(-)} &= \frac{g^2 m_{j'}}{32\pi^2} \left\{ \delta_{jj'} \left(1 + \frac{m_j^2}{2m_W^2} \Delta \right) - V_{j'l}^\dagger V_{lj} \frac{m_l^2}{2m_W^2} \left[3\Delta + I\left(m_j^2, m_l\right) + J\left(m_j^2, m_l\right) \right] \right. \\
&\quad \left. + V_{j'l}^\dagger V_{lj} \left(1 + \frac{m_j^2}{2m_W^2} \right) \left[I\left(m_j^2, m_l\right) - J\left(m_j^2, m_l\right) \right] \right\}, \\
\delta m_{j'j}^{(+)} &= \frac{g^2 m_j}{32\pi^2} \left\{ \delta_{jj'} \left(1 + \frac{m_j^2}{2m_W^2} \Delta \right) - V_{j'l}^\dagger V_{lj} \frac{m_l^2}{2m_W^2} \left[3\Delta + I\left(m_j^2, m_l\right) + J\left(m_j^2, m_l\right) \right] \right. \\
&\quad \left. + V_{j'l}^\dagger V_{lj} \left(1 + \frac{m_{j'}^2}{2m_W^2} \right) \left[I\left(m_j^2, m_l\right) - J\left(m_j^2, m_l\right) \right] \right\},
\end{aligned} \tag{42}$$

where l labels the virtual up-type quark in the self-energy loop.

We emphasize that Eqs. (39) and (42) contain all the off-diagonal sm contributions since they only arise from Fig. 1(a) and the analogous diagrams involving the down-type quarks. On the other hand, there are many additional diagonal sm contributions from other diagrams.

Writing the mass counterterm matrix for the down-type quarks in the form

$$\begin{pmatrix} \delta m_{dd} & \delta m_{ds} & \delta m_{db} \\ \delta m_{sd} & \delta m_{ss} & \delta m_{sb} \\ \delta m_{bd} & \delta m_{bs} & \delta m_{bb} \end{pmatrix}, \tag{43}$$

we choose δm_{dd}, δm_{ss}, and δm_{bb} to cancel the diagonal sm contributions, and δm_{sd}, δm_{bd}, and δm_{bs} to cancel the corresponding off-diagonal terms. The hermiticity constraint implies then that the finite parts of the sm contributions are not fully canceled in the reverse ds, db, and sb channels. We find that, after the mass renormalization is implemented, the residual contributions involving the top quark in the self-energy loop are of first order in the small ratios, while the others are of second order. Nonetheless, as shown in Appendix A, their contributions to the $W \to q_i + \overline{q}_j$ amplitudes are also very small. In particular, the smallness in the ds channel arises because some contributions are of second order in m_q^2/m_W^2 $(q \neq t)$ and others are proportional to m_s^2/m_t^2 with very small CKM coefficients.

We note that, in these renormalization prescriptions, the residual sm contributions are convergent in the limit $m_{i'} \to m_i$ or $m_{j'} \to m_j$, since the singularities of the virtual propagators $i(\not{p} - m_{i'})^{-1}$ and $i(\not{p} - m_{j'})^{-1}$ are canceled, a characteristic property of wfr contributions. Thus, these residual sm terms can be regarded as additional finite and gauge-independent contributions to wave-function renormalization that happen to be numerically very small.

It is also interesting to note that these renormalization prescriptions imply that the sm contributions are fully canceled when the u or d quarks or antiquarks are the external, on-shell particles. This is of special interest since V_{ud}, the relevant parameter in the $W \to u + \overline{d}$ amplitude, is by far the most accurately measured CKM matrix element [3, 4].

IV. DIAGONALIZATION OF THE MASS COUNTERTERMS AND DERIVATION OF THE CKM COUNTERTERM MATRIX

In Sec. III, we showed explicitly how the UV-divergent parts of the one-loop sm contributions associated with external quark legs [cf. Fig. 1(a)] can be canceled by suitably adjusting the non-diagonal mass counterterm matrix. By imposing on-shell renormalization conditions, we also showed how the finite parts of such contributions can be canceled up to the constraints imposed by the hermiticity of the mass matrix. We also recall that, in our formulation, the sm contributions and, consequently, also the mass counterterms are explicitly gauge independent.

In this section, we discuss the diagonalization of the complete mass matrix of Eq. (34), which includes the renormalized and counterterm mass matrices. We show how this procedure generates a CKM counterterm matrix that automatically satisfies the basic properties of gauge independence and unitarity.

Starting with Eq. (34), we implement a biunitary transformation that diagonalizes the matrix $m - \delta m^{(-)}$. Specifically, we consider the transformations

$$\psi_L \;=\; U_L \hat{\psi}_L, \tag{44}$$

$$\psi_R \;=\; U_R \hat{\psi}_R, \tag{45}$$

and choose the unitary matrices U_L and U_R so that

$$U_R^\dagger \left(m - \delta m^{(-)}\right) U_L = \mathcal{D}, \tag{46}$$

where $\mathcal{D}$ is diagonal and real. From Eq. (46), it follows that

$$U_L^\dagger \left(m - \delta m^{(-)\dagger}\right) \left(m - \delta m^{(-)}\right) U_L = \mathcal{D}^2, \tag{47}$$

which, through $\mathcal{O}(g^2)$, reduces to

$$U_L^\dagger \left(m^2 - m\delta m^{(-)} - \delta m^{(-)\dagger} m\right) U_L = \mathcal{D}^2. \tag{48}$$

Writing $U_L = 1 + ih_L$, where h_L is hermitian and of $\mathcal{O}(g^2)$, we have

$$m^2 + i(m^2 h_L - h_L m^2) - m\delta m^{(-)} - \delta m^{(-)\dagger} m = \mathcal{D}^2, \tag{49}$$

where we have neglected terms of $\mathcal{O}(g^4)$. Recalling that, in our formulation, m is diagonal (cf. Sec. III) and taking the ii' component, Eq. (49) becomes

$$m_i^2 \delta_{ii'} + i\left(m_i^2 - m_{i'}^2\right)(h_L)_{ii'} - m_i \delta m_{ii'}^{(-)} - \delta m_{ii'}^{(-)\dagger} m_{i'} = \mathcal{D}_i^2 \delta_{ii'}. \tag{50}$$

For diagonal terms, with $i = i'$, the term proportional to $(h_L)_{ii'}$ does not contribute. Furthermore, Eq. (39) tells us that $\delta m_{ii}^{(-)} = \delta m_{ii}^{(+)}$. Consequently, for diagonal elements of the mass counterterm matrix, one has $\delta m_{ii}^{(-)} a_- + \delta m_{ii}^{(+)} a_+ = \delta m_i$, where $\delta m_i = \delta m_{ii}^{(-)} = \delta m_{ii}^{(+)}$. We note that the hermiticity condition of Eq. (40) implies that δm_i is real. Therefore, for $i = i'$, Eq. (50) reduces to $m_i^2 - 2m_i \delta m_i = \mathcal{D}_i^2$ or, equivalently, through $\mathcal{O}(g^2)$, to

$$\mathcal{D}_i = m_i - \delta m_i. \tag{51}$$

In order to satisfy Eq. (50) for $i \neq i'$, we need to cancel the off-diagonal contributions $m_i \delta m_{ii'}^{(-)} + \delta m_{ii'}^{(-)\dagger} m_{i'}$. This is achieved by adjusting the non-diagonal elements of h_L according to

$$i(h_L)_{ii'} = \frac{m_i \delta m_{ii'}^{(-)} + \delta m_{ii'}^{(+)} m_{i'}}{m_i^2 - m_{i'}^2} \qquad (i \neq i'), \tag{52}$$

where we have employed the hermiticity relation of Eq. (35). Since the diagonal elements $(h_L)_{ii}$ do not contribute to Eq. (50), it is convenient to choose $(h_L)_{ii} = 0$. In Appendix B, we show that the alternative selection $(h_L)_{ii} \neq 0$ has no physical effect on the $W q_i \overline{q}_j$ interactions.

Returning to Eq. (46) and writing $U_R = 1 + i h_R$, one finds that h_R is obtained from h_L by substituting $\delta m^{(-)} \leftrightarrow \delta m^{(+)}$ in Eq. (52). Thus,

$$i(h_R)_{ii'} = \frac{m_i \delta m_{ii'}^{(+)} + \delta m_{ii'}^{(-)} m_{i'}}{m_i^2 - m_{i'}^2} \qquad (i \neq i'). \tag{53}$$

In fact, substituting $U_L = 1 + i h_L$ and $U_R = 1 + i h_R$ in Eq. (46) and employing Eqs. (52) and (53), one readily verifies that the l.h.s. of Eq. (46) is indeed diagonal through $\mathcal{O}(g^2)$. Furthermore, one recovers Eq. (51).

The above analysis is carried out separately to diagonalize the mass matrices of the up- and down-type quarks. Thus, we obtain two pairs of h_L and h_R matrices: h_L^U and h_R^U for the up-type quarks and h_L^D and h_R^D for the down-type quarks.

Next, we analyze the effect of transformation (44) on the $W q_i \overline{q}_j$ interaction. Following standard conventions, the latter is given by

$$\mathcal{L}_{W q_i \overline{q}_j} = -\frac{g_0}{\sqrt{2}} \overline{\psi}_i^U V_{ij} \gamma^\lambda a_- \psi_j^D W_\lambda + \text{h.c.}, \tag{54}$$

where ψ_i^U $(i = u, c, t)$ and ψ_j^D $(j = d, s, b)$ are the fields of the up- and down-type quarks, respectively, W_λ is the field that annihilates a W^+ boson or creates a W^- boson, g_0 is the bare $\mathrm{SU}(2)_L$ coupling, and V_{ij} are the elements of the unitary CKM matrix. Alternatively,

in matrix notation, we have

$$\mathcal{L}_{Wq_i\overline{q}_j} = -\frac{g_0}{\sqrt{2}}\overline{\psi}_L^U V\gamma^\lambda\psi_L^D W_\lambda + \text{h.c.}. \tag{55}$$

It is important to note that, in the formulation of this paper, in which the UV-divergent sm terms are canceled by the mass counterterms and the proof of finiteness of the other contributions to the $W \to q_i + \overline{q}_j$ amplitude after the renormalization of g_0 is the same as in the unmixed case (cf. Sec. II C), V_{ij} are finite quantities.

Inserting Eq. (44) in Eq. (55), we find, through terms of $\mathcal{O}(g^2)$, that

$$\mathcal{L}_{Wq_i\overline{q}_j} = -\frac{g_0}{\sqrt{2}}\overline{\hat{\psi}}_L^U (V-\delta V)\gamma^\lambda\hat{\psi}_L^D W_\lambda + \text{h.c.}, \tag{56}$$

where

$$\delta V = i\left(h_L^U V - V h_L^D\right). \tag{57}$$

One readily verifies that $V - \delta V$ satisfies the unitarity condition through terms of $\mathcal{O}(g^2)$, namely

$$(V-\delta V)^\dagger (V-\delta V) = 1 + \mathcal{O}(g^4). \tag{58}$$

Since V is finite and unitary, it is identified with the renormalized CKM matrix. On the other hand, in the $(\hat{\psi}_L, \hat{\psi}_R)$ basis, in which the complete quark mass matrices are diagonal, δV and $V_0 = V - \delta V$ represent the counterterm and bare CKM matrices, respectively.

We now show explicitly that the $ih_L^U V$ term in δV leads to the same off-diagonal contribution to the $W \to q_i + \overline{q}_j$ amplitude as the insertion of the mass counterterms $\delta m^{U(-)}$ and $\delta m^{U(+)}$ in the external up-type-quark line. Indeed, the $ih_L^U V$ contribution is given by

$$\mathcal{M}(ih_L^U V) = \frac{ig}{\sqrt{2}}\overline{u}_i i\left(h_L^U\right)_{ii'} V_{i'j}\gamma^\lambda a_- v_j \epsilon_\lambda, \tag{59}$$

where, again, u_i and v_j are the external up- and down-type-quark spinors, respectively, and ϵ_λ is the W-boson polarization four-vector. Inserting Eq. (52), Eq. (59) becomes

$$\mathcal{M}(ih_L^U V) = \frac{ig}{\sqrt{2}}\overline{u}_i \frac{m_i^U \delta m_{ii'}^{U(-)} + \delta m_{ii'}^{U(+)} m_{i'}^U}{\left(m_i^U\right)^2 - \left(m_{i'}^U\right)^2} V_{i'j}\gamma^\lambda a_- v_j \epsilon_\lambda, \tag{60}$$

where it is understood that $i \neq i'$ and the label $Q = U, D$, which we had suppressed from Eq. (34) through Eq. (53), is again displayed. On the other hand, the off-diagonal mass counterterm insertion in the external up-type-quark line is given by

$$\mathcal{M}\left(\delta m^{U(-)}, \delta m^{U(+)}\right) = -\frac{ig}{\sqrt{2}}\overline{u}_i i\left(\delta m_{ii'}^{U(-)} a_- + \delta m_{ii'}^{U(+)} a_+\right)\frac{i}{\not{p} - m_{i'}^U} V_{i'j}\gamma^\lambda a_- v_j \epsilon_\lambda. \tag{61}$$

Rationalizing the propagator $i(\not{p} - m_{i'}^U)^{-1}$, one finds after some elementary algebra that Eq. (60) coincides with Eq. (61). An analogous calculation shows that the $-iVh_L^D$ term in δV leads to the same off-diagonal contribution to the $W \to q_i + \overline{q}_j$ amplitude as the insertion of the mass counterterms $\delta m^{D(-)}$ and $\delta m^{D(+)}$ in the external down-type-quark line. Since the mass counterterms are adjusted to cancel the off-diagonal sm contributions to the extent allowed by the hermiticity of the mass matrix, the same is true of the CKM counterterm matrix δV. In particular, δV fully cancels the UV-divergent part of the off-diagonal sm contributions. As mentioned above, in the formulation of this section, the complete mass matrix is diagonal, with elements of the form given in Eq. (51), where m_i are the renormalized masses and δm_i the corresponding mass counterterms. The quantities δm_i are then adjusted to fully cancel the diagonal sm corrections in the external legs, in analogy with QED. As also explained above, the additional UV divergences arising from the wfr contributions, proper vertex diagrams, and renormalization of g_0 cancel among themselves as in the single-generation case.

For completeness, we explicitly exhibit the counterterm of the CKM matrix in component form:

$$\begin{aligned}
\delta V_{ij} &= i\left[\left(h_L^U\right)_{ii'} V_{i'j} - V_{ij'}\left(h_L^D\right)_{j'j}\right] \\
&= \frac{m_i^U \delta m_{ii'}^{U(-)} + \delta m_{ii'}^{U(+)} m_{i'}^U}{\left(m_i^U\right)^2 - \left(m_{i'}^U\right)^2} V_{i'j} - V_{ij'} \frac{m_{j'}^D \delta m_{j'j}^{D(-)} + \delta m_{j'j}^{D(+)} m_j^D}{\left(m_{j'}^D\right)^2 - \left(m_j^D\right)^2},
\end{aligned} \tag{62}$$

where we have used Eqs. (52), (53), and (57) and it is understood that $i \neq i'$ in the first term and $j' \neq j$ in the second one.

We note that Eq. (62) involves contributions proportional to $\left(m_i^U - m_{i'}^U\right)^{-1}$ and $\left(m_{j'}^D - m_j^D\right)^{-1}$, which would become very large if the masses of different flavors were nearly degenerate. This is to be expected, since the role of these counterterms is precisely to cancel the analogous sm contributions to Eq. (3) arising from Fig. 1, so that the renormalized expressions are indeed free from such singular behavior.

It is important to emphasize that, in this formulation, both the renormalized CKM matrix V and its bare counterpart $V_0 = V - \delta V$ are explicitly gauge independent and satisfy the unitarity constraints $V^\dagger V = 1$ and $V_0^\dagger V_0 = 1$, respectively, through the order of the calculation. The explicit construction of the CKM counterterm matrix, as given in Eqs. (57) and (62), satisfying this important property, is the main result of this section.

V. CONCLUSIONS

In this paper we have presented a natural on-shell framework to renormalize the CKM matrix at the one-loop level. We have shown the gauge independence of the sm contributions and discussed their cancellation in two equivalent formulations: the first one involves non-diagonal mass counterterms, while the second one is based on a CKM counterterm matrix. We have also established the important fact that the proof of gauge independence and finiteness of the remaining one-loop corrections to the $W \to q_i + \overline{q}_j$ amplitude can be reduced to the single-generation case. The analysis has led us to an explicit expression for the CKM counterterm matrix δV_{ij}, given in Eq. (62), that satisfies the basic property of gauge independence and is consistent with the unitarity of both $V_0 = V - \delta V$ and V, the bare and renormalized CKM matrices. Furthermore, it leads to renormalized amplitudes that are non-singular in the limit in which any two fermions become mass degenerate. Because V is finite, gauge independent, and unitary, its elements can be identified with the experimentally measured CKM matrix elements.

APPENDIX A: RESIDUAL SELF-MASS CORRECTIONS C_{ij}

In this appendix we evaluate the finite and gauge-independent residual contributions $-C_{ij}\overline{u}_i\gamma^\lambda a_- v_j \epsilon_\lambda$ to the $W \to q_i + \overline{q}_j$ amplitude that are not removed in our mass renormalization prescription due to the restrictions imposed by the hermiticity of the mass matrices. Inserting Eq. (29) and its counterpart for down-quark matrices in the expression for the $W \to q_i + \overline{q}_j$ amplitude and implementing our mass renormalization subtractions, we find

the residual sm corrections C_{ij} to be

$$
\begin{aligned}
C_{ij} \;=\; & \frac{g^2}{32\pi^2}\left\{\frac{V_{il}V^\dagger_{li'}V_{i'j}}{m_i^2-m_{i'}^2}\left[\left(m_i^2+m_{i'}^2+\frac{m_i^2m_{i'}^2}{m_W^2}\right)\left(I(p^2,m_l)-J(p^2,m_l)\right)\right.\right. \\
& \left.\left.-\frac{m_l^2}{2m_W^2}\left(m_i^2+m_{i'}^2\right)\left(I(p^2,m_l)+J(p^2,m_l)\right)\right]_{p^2=m_{i'}^2}^{p^2=m_i^2}\right. \\
& +\frac{V_{ij'}V^\dagger_{j'k}V_{kj}}{m_j^2-m_{j'}^2}\left[\left(m_j^2+m_{j'}^2+\frac{m_j^2m_{j'}^2}{m_W^2}\right)\left(I(p^2,m_k)-J(p^2,m_k)\right)\right. \\
& \left.\left.-\frac{m_k^2}{2m_W^2}\left(m_j^2+m_{j'}^2\right)\left(I(p^2,m_k)+J(p^2,m_k)\right)\right]_{p^2=m_{j'}^2}^{p^2=m_j^2}\right\}, \qquad \text{(A1)}
\end{aligned}
$$

where the l and k summations are over $l=d,s,b$ and $k=u,c,t$, and it is understood that only terms with $(i,i')=(c,u),(t,u),(t,c)$ or $(j',j)=(d,s),(d,b),(s,b)$ are included.

For the reader's convenience, we list compact analytic results for the functions $I(p^2,m_l)$ and $J(p^2,m_l)$ defined in Eq. (20):

$$
\begin{aligned}
I(p^2,m_l) \;=\; & -2+\frac{p^2+m_l^2-m_W^2}{2p^2}\ln\frac{m_l^2}{m_W^2}-2\frac{m_lm_W}{p^2}f\left(\frac{p^2-m_l^2-m_W^2}{2m_lm_W}\right), \\
J(p^2,m_l) \;=\; & \frac{1}{2p^2}\left[-m_l^2+m_W^2+m_l^2\ln\frac{m_l^2}{m_W^2}+\left(p^2-m_l^2+m_W^2\right)I(p^2,m_l)\right], \qquad \text{(A2)}
\end{aligned}
$$

where

$$
f(x)=\begin{cases}\sqrt{x^2-1}\cosh^{-1}(-x) & \text{if } x\le -1,\\ -\sqrt{1-x^2}\cos^{-1}(-x) & \text{if } -1<x\le 1,\\ \sqrt{x^2-1}\left(-\cosh^{-1}x+i\pi\right) & \text{if } x>1.\end{cases} \qquad \text{(A3)}
$$

In practical applications of Eq. (A2), one encounters strong numerical cancellations between the various terms when $|p^2|\ll m_W^2$. It is then advantageous to employ the expansions of $I(p^2,m_l)$ and $J(p^2,m_l)$ in p^2 about $p^2=0$,

$$
\begin{aligned}
I(p^2,m_l) \;=\; & -1+\frac{m_l^2}{m_l^2-m_W^2}\ln\frac{m_l^2}{m_W^2}+\frac{p^2}{\left(m_l^2-m_W^2\right)^2}\left(-\frac{m_l^2+m_W^2}{2}+\frac{m_l^2m_W^2}{m_l^2-m_W^2}\ln\frac{m_l^2}{m_W^2}\right) \\
& +\mathcal{O}\left((p^2)^2\right), \\
J(p^2,m_l) \;=\; & \frac{1}{2\left(m_l^2-m_W^2\right)}\left(\frac{-m_l^2+3m_W^2}{2}+\frac{m_l^2\left(m_l^2-2m_W^2\right)}{m_l^2-m_W^2}\ln\frac{m_l^2}{m_W^2}\right) \\
& +\frac{p^2}{\left(m_l^2-m_W^2\right)^3}\left(\frac{-m_l^4+5m_l^2m_W^2+2m_W^4}{6}-\frac{m_l^2m_W^4}{m_l^2-m_W^2}\ln\frac{m_l^2}{m_W^2}\right) \\
& +\mathcal{O}\left((p^2)^2\right). \qquad \text{(A4)}
\end{aligned}
$$

TABLE I: Residual self-mass corrections C_{ij} as evaluated from Eq. (A1) in the form $(\mathrm{Re}\, C_{ij}, \mathrm{Im}\, C_{ij})$.

i \ j	d	s	b
u	$(0, 0)$	$(-1.6 \times 10^{-12}, -5.2 \times 10^{-13})$	$(-3.2 \times 10^{-9}, 4.9 \times 10^{-9})$
c	$(4.5 \times 10^{-13}, 1.2 \times 10^{-13})$	$(4.9 \times 10^{-13}, 1.5 \times 10^{-13})$	$(-6.1 \times 10^{-8}, 2.1 \times 10^{-12})$
t	$(-1.5 \times 10^{-9}, -7.9 \times 10^{-8})$	$(-1.6 \times 10^{-7}, 3.7 \times 10^{-7})$	$(-4.0 \times 10^{-9}, 1.6 \times 10^{-8})$

The standard parameterization of the CKM matrix, in terms of the three angles θ_{12}, θ_{23}, and θ_{13} and the phase δ, reads [2]:

$$V = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13} \end{pmatrix}, \quad \text{(A5)}$$

where $s_{ij} = \sin\theta_{ij}$ and $c_{ij} = \cos\theta_{ij}$. An equivalent set of four real parameters are λ, A, $\overline{\rho}$, and $\overline{\eta}$, which are related to θ_{12}, θ_{23}, θ_{13}, and δ as [2]

$$\begin{aligned} s_{12} &= \lambda, \\ s_{23} &= A\lambda^2, \\ s_{13}e^{i\delta} &= \frac{A\lambda^3(\overline{\rho} + i\overline{\eta})\sqrt{1 - A^2\lambda^4}}{\sqrt{1-\lambda^2}\,[1 - A^2\lambda^4(\overline{\rho} + i\overline{\eta})]}. \end{aligned} \quad \text{(A6)}$$

In our numerical evaluation of Eq. (A1), we identify $g^2/(4\pi) = \hat{\alpha}(m_Z)/\sin^2\hat{\theta}_W(m_Z)$ and employ the values $\hat{\alpha}(m_Z) = 1/127.918$ and $\sin^2\hat{\theta}_W(m_Z) = 0.23122$ [2]. We take the W-boson mass to be $m_W = 80.403$ GeV [2]. As for the quark masses, we use the values $m_u = 62$ MeV, $m_d = 83$ MeV, $m_s = 215$ MeV, $m_c = 1.35$ GeV, $m_b = 4.5$ GeV [3] and $m_t = 172.7$ GeV [2]; in the case of the lighter quarks, these correspond to effective masses that are especially appropriate for electroweak analyses like ours. We evaluate the CKM matrix elements from Eqs. (A5) and (A6) using the values $\lambda = 0.2272$, $A = 0.818$, $\overline{\rho} = 0.221$, and $\overline{\eta} = 0.340$ [2].

In Table I, we present our results for the residual sm corrections C_{ij}. As explained in Sec. III, in our renormalization prescription $C_{ud} = 0$. As shown in Table I, for the other $W \to q_i + \overline{q}_j$ amplitudes, the real and imaginary parts of C_{ij} are very small. For example, the fractional corrections of $\mathrm{Re}\, C_{ij}$ with respect to the real parts of the corresponding Born

amplitude couplings, namely $\mathrm{Re}\, C_{ij}/\,\mathrm{Re}\, V_{ij}$, reach a maximum value of 4×10^{-6} for $t \to W+s$ and are much smaller for several other cases. It is important to note that the C_{ij} are non-singular in the limits $m_{i'} \to m_i$ or $m_{j'} \to m_j$, since the $\left(m_i^2 - m_{i'}^2\right)^{-1}$ and $\left(m_j^2 - m_{j'}^2\right)^{-1}$ singularities are canceled by the subtraction procedure in Eq. (A1). For this reason, as also explained in Sec. III, these residual corrections can be regarded as additional finite and gauge-independent wfr contributions, which happen to be very small.

APPENDIX B: CASE $(h_L)_{ii} \neq 0$

Since the diagonal elements $(h_L)_{ii}$ do not contribute to the diagonalization condition of Eq. (50), in the analysis of Sec. IV, we chose $(h_L)_{ii} = 0$. We now show that the alternative choice $(h_L)_{ii} \neq 0$ has no physical effect on the $Wq_i\overline{q}_j$ coupling though $\mathcal{O}(g^2)$. As explained in Sec. IV, the biunitary transformation of Eqs. (44) and (45) leads to a $Wq_i\overline{q}_j$ interaction described through terms of $\mathcal{O}(g^2)$ by Eqs. (56) and (57). Writing these expressions in component form and separating out the contributions involving the diagonal elements of h^U and h^D, we obtain an expression proportional to

$$\overline{\hat{\psi}}_i^{(U)} \left[V_{ij} - i\left(h_L^U\right)_{ii} V_{ij} + V_{ij} i\left(h_L^D\right)_{jj}\right] \gamma^\lambda a_- \hat{\psi}_j^{(D)}, \tag{B1}$$

which can be written as

$$\overline{\hat{\psi}}_i^{(U)} \left[1 - i\left(h_L^U\right)_{ii}\right] V_{ij} \left[1 + i\left(h_L^D\right)_{jj}\right] \gamma^\lambda a_- \hat{\psi}_j^{(D)} + \mathcal{O}(g^4). \tag{B2}$$

In turn, this can be expressed as

$$\overline{\hat{\psi}}_i^{(U)} \exp\left[-i\left(h_L^U\right)_{ii}\right] V_{ij} \exp\left[i\left(h_L^D\right)_{jj}\right] \gamma^\lambda a_- \hat{\psi}_j^{(D)} + \mathcal{O}(g^4). \tag{B3}$$

Since h_L^U and h_L^D are hermitian, the diagonal elements are real. Thus $\exp\left[-i\left(h_L^U\right)_{ii}\right]$ and $\exp\left[i\left(h_L^D\right)_{jj}\right]$ are multiplicative phases that can be absorbed in redefinitions of the $\hat{\psi}_j^{(U)}$ and $\hat{\psi}_j^{(D)}$ fields.
